LUTH HOSPITAL DASHBOARD — KEY INSIGHTS

Outcome distribution is nearly balanced across all four categories — Recovered 24%, Referred 27.6%, Under Observation 25.2%, and Deceased 23.2% — instead of recovery dominating as expected, pointing to a systemic issue in treatment effectiveness rather than normal variation.

Average patient satisfaction is low at 3.0/5, consistent with the weak recovery rate, suggesting satisfaction reflects clinical outcomes and not just service quality.

Recovery rate varies sharply by doctor, from 18% to 30%, and does not track directly with patient load — this points to case-mix or department-level effects that need further investigation before drawing conclusions about individual doctor performance.

Average cost is inversely related to age: the Child (0-12) group has the highest average cost, decreasing through to Seniors, the opposite of typical expectation — suggesting pediatric cases require more intensive or urgent intervention.

Patient volume is unevenly distributed across departments, with Orthopedics and Cardiology carrying the highest load (140+ patients) and Emergency the lowest, indicating staffing and resource allocation may need review.

Average length of stay is high at 8.02 days alongside an average cost per visit of ₦132K, while the monthly visit trend stays relatively flat with no strong seasonality — allowing capacity planning to stay consistent year-round rather than reactive.

Gender split (48% female / 52% male) and payment method distribution show no meaningful imbalance, indicating no access-equity concern on these dimensions.
